

VFX Creator – Universal Shader

Support and suggestions: biostart61@gmail.com

If you have any questions or ideas for improvement, feel free to contact us by email.

Please consider leaving a review – it really helps the development of the package!

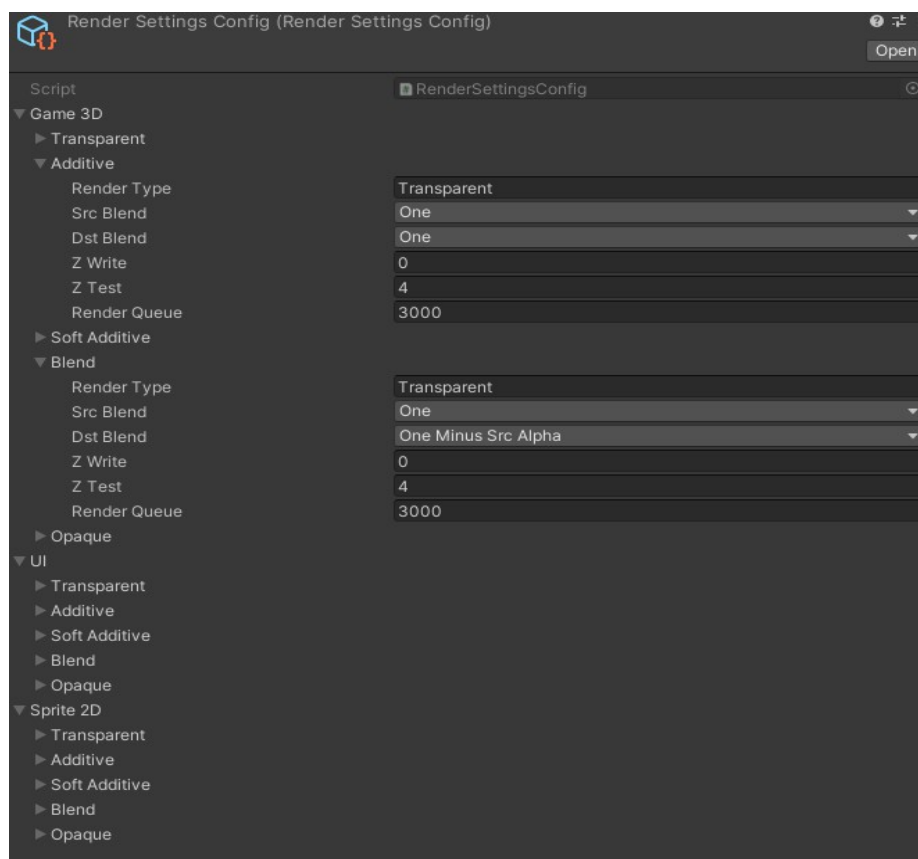

For URP support, open Package/URP_Support

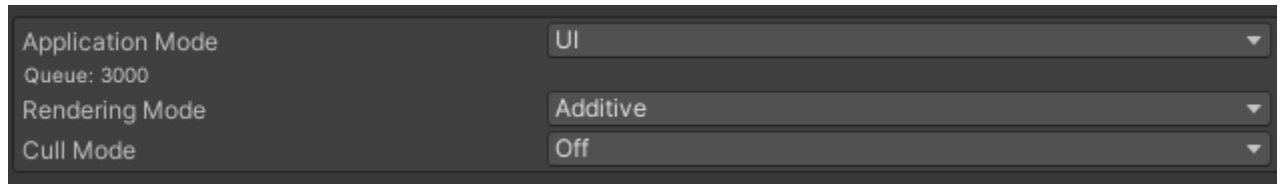

For textures with a transparent background, it is recommended to enable Alpha From Grayscale, so that the texture's brightness controls transparency.

Adjust Alpha From Grayscale, HDR Color, Brightness, and Contrast settings to achieve the desired particle visual effect.

RenderSettingsConfig is a ScriptableObject that contains the default render settings for visual effects (VFX) materials.

It is used when creating a new VFX material to automatically assign correct values for transparency, additive blending, soft particles, and other rendering parameters.

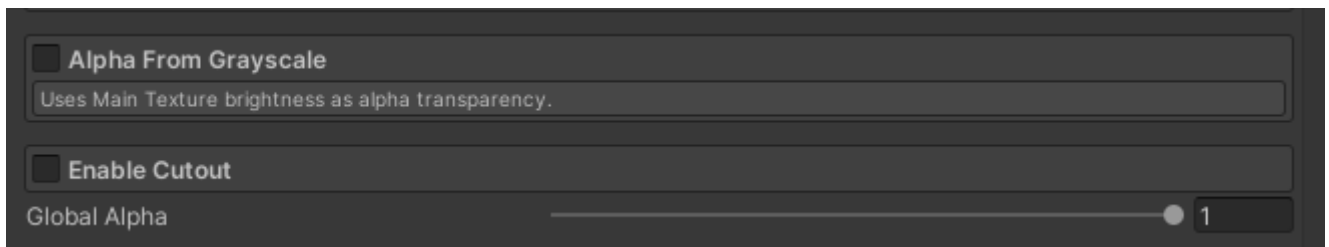

Application Mode – Defines the type of usage for the material (e.g., 3D Game, UI, 2D Sprite) and determines which default render settings are applied.

Rendering Mode – Specifies how the material blends with the background. Options: Transparent, Additive, SoftAdditive, Blend, Opaque, **Other** (allows manual selection of blend settings).

Cull Mode – Controls which faces of the geometry are rendered: Back, Front, or Off (no culling).

Alpha From Grayscale – emulates grayscale for the alpha channel, using texture brightness to control transparency.

Enable Cutout – suitable for creating sharp edges, as seen in stylized visual effects.

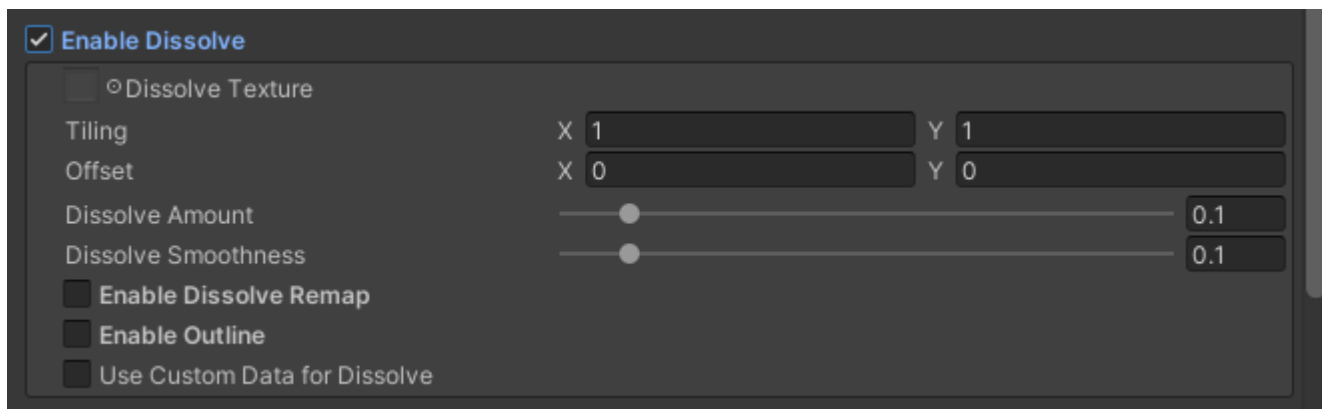

Global Alpha – controls the overall transparency of the material.

Mask Texture – mask texture that defines the area of effect on the object.

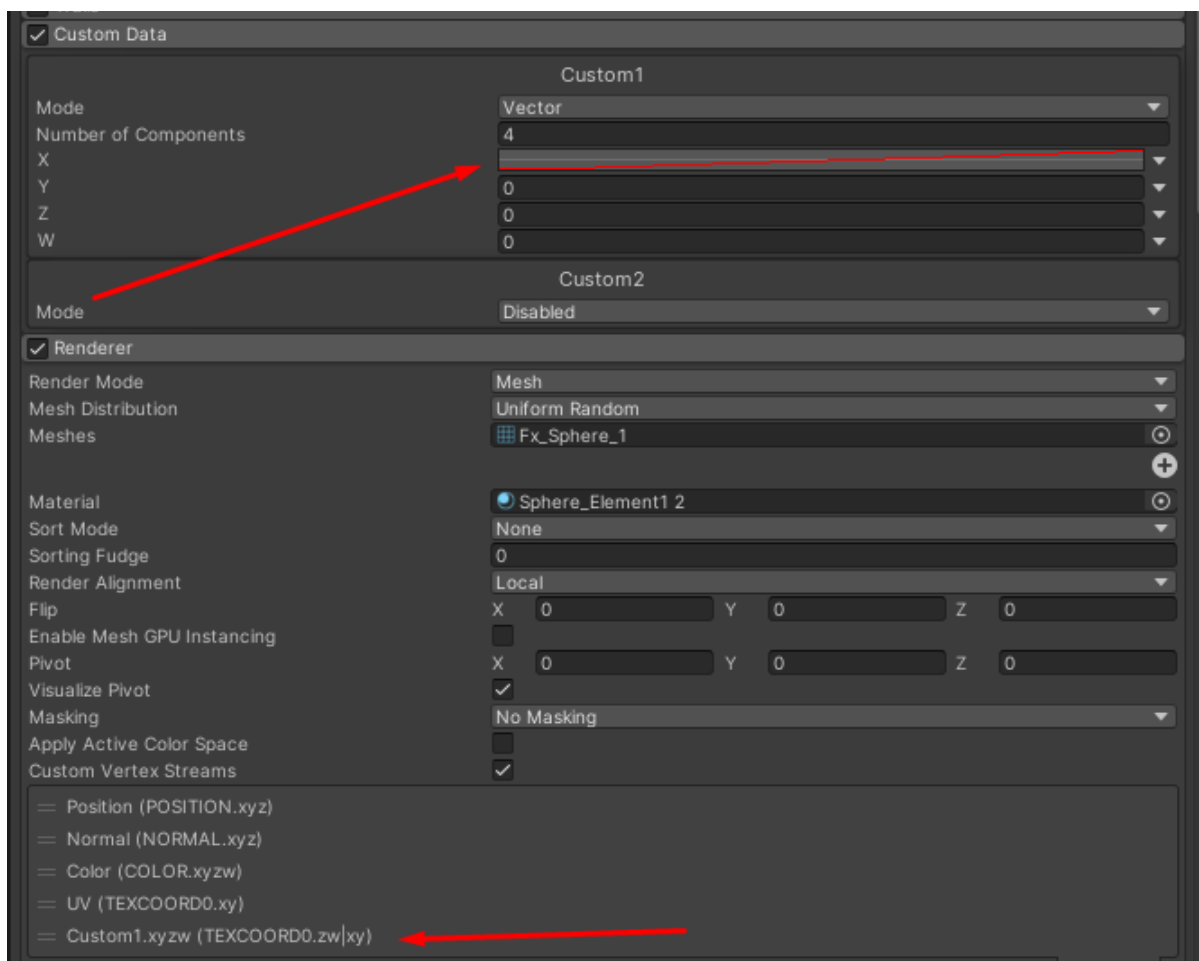

Enable Flow Mask – adds animation subtracted from the main mask, creating a flowing or moving effect.

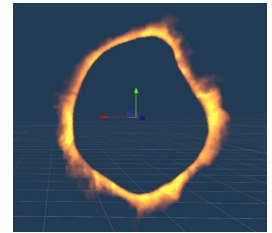

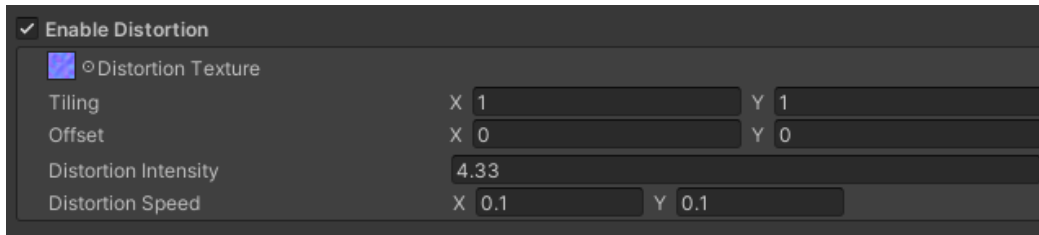

Enable Mask Noise – applies noise to the mask for more organic and random effect distribution.

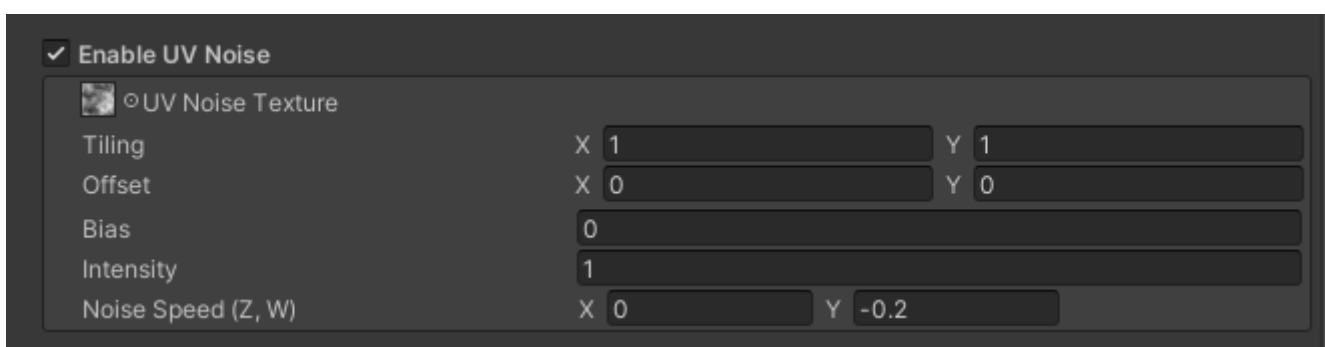

The **Dissolve** effect allows an object to gradually “dissolve” using a texture, creating a disappearing or destruction effect.

The **Use Custom Data for Dissolve** option uses **Custom Data** from the particle system, automatically controlling the dissolve effect based on the particle’s lifetime.

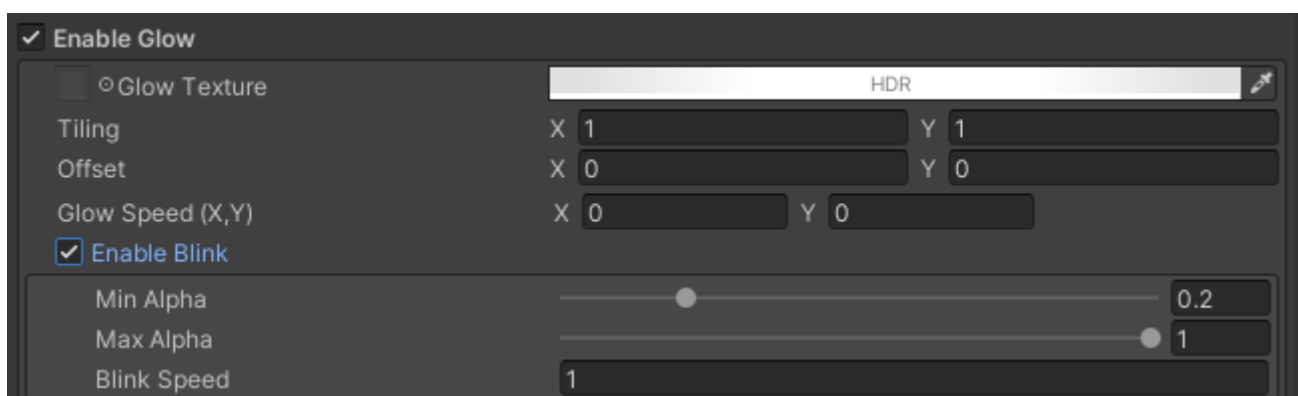

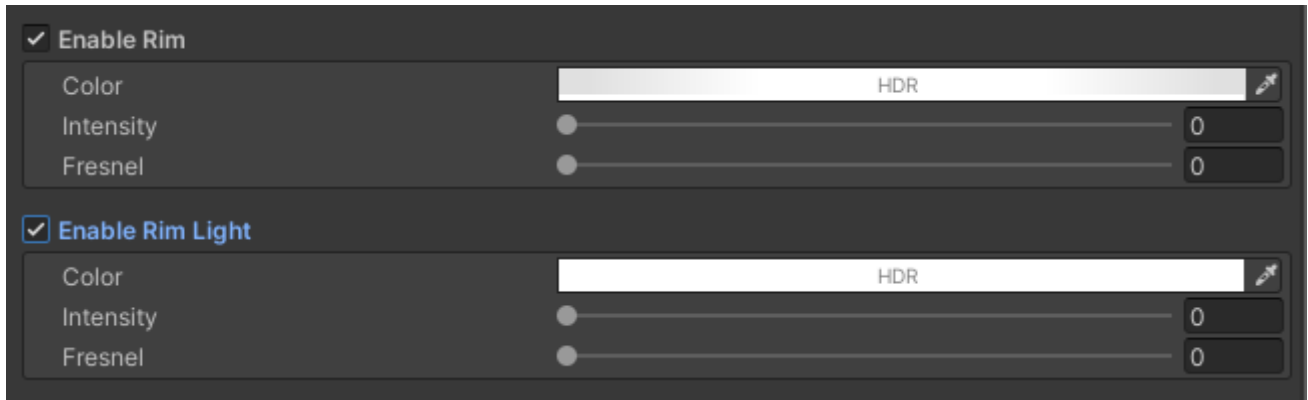

Distortion warps the image or particles, creating a sense of motion or deformation. For a more pronounced effect, it is recommended to use a **Normal Map**.

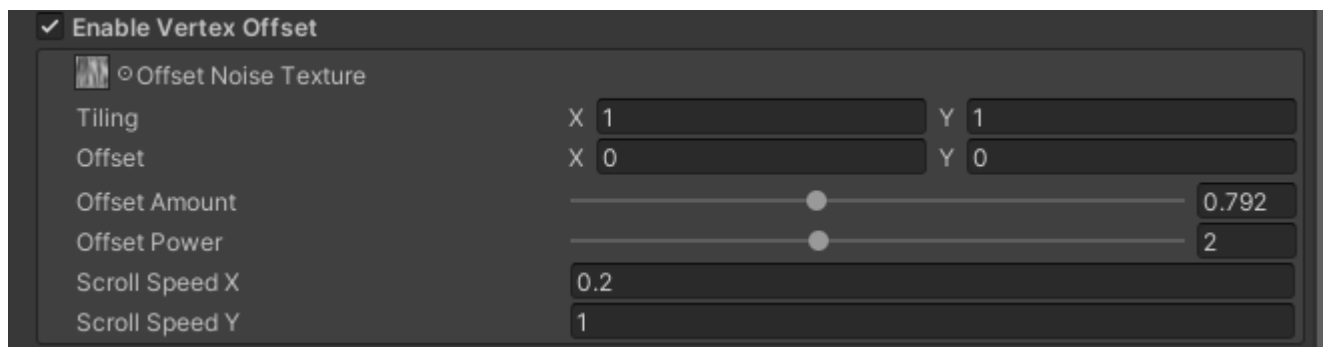

Noise adds random variations or noise to the texture or particles, creating a more dynamic and lively motion effect.

Glow is suitable for creating a glowing effect, either static or animated. **Blink** makes the glow periodically blink, creating a pulsing effect.

Rim creates a rim effect on the texture, emphasizing the object's shape by highlighting its edges. **Rim Light** adds extra lighting on the object's edges, simulating reflected or backlight.

Vertex Offset allows displacing the vertices of an object based on a texture or noise, creating deformation effects and dynamic surface movement.

Soft Particles soften the edges of particles when intersecting with scene geometry, preventing harsh clipping and creating smoother blending with the environment.
